Tenth European Workshop on Automatic Differentiation

Outline

1 Motivation

- Generating adjoint code for Matlab
- Scalar adjoint rules are not enough

2 Analysis

- Adjoint rules
- Example statement
- Intermediate canonicalization

3 Solution

- Recursive construction
- XSLT implementation

4 Results and Conclusion

- An example
- Conclusion

Extending our tool ADiMat with reverse mode

ADiMat implements AD *source transformation* of Matlab code. Consider a function with signature **function** $z = f(a)$

- Forward mode: `adimat f.m` produces
function $[g_z, z] = g_f(g_a, a)$
- Reverse mode: `admproc f.m` produces
function $[a_a, z] = a_f(a, a_z)$
via *XSL transformations*

In both cases the derivative variables can be either native doubles, which (in general) results in scalar mode or one can use one of several derivative classes, which allows vector mode.

- Conclusion

Adjoint code rules

Transformation rules found in the literature are for scalar valued variables

- Consider $z = e(x)$
- Adjoint statement: $\bar{x} += \frac{\partial e}{\partial x} \bar{z}$
- What happens when $e(x) = a * x * b$ and the variables are matrices?
- What is $\frac{\partial e}{\partial x}$ in this case?
- Dimensions of $\frac{\partial e}{\partial x}$ and \bar{z} will not fit in general.

Outline

1 Motivation

- Generating adjoint code for Matlab
- Scalar adjoint rules are not enough

2 Analysis

- Adjoint rules
- Example statement
- Intermediate canonicalization

3 Solution

- Recursive construction
- XSLT implementation

4 Results and Conclusion

- An example
- Conclusion

Adjoint rules: Sine

- Sine: $Z = \sin(A)$

- $\bar{A} += \bar{Z}.* \cos(A)$

- Derivative variables have the same dimension as the variable they are associated with.
- Use upper case letters to indicate rule place holders.
- The place where $dZ = \bar{Z}$ occurs is the *adjoint position*.

Adjoint rules: Multiplication

- Multiplication

- $Z = A * B$, w.r.t. A

- $\bar{A} += \bar{Z} * B^T$

- $Z = A * B$, w.r.t. B

- $\bar{B} += A^T * \bar{Z}$

Outline

1 Motivation

- Generating adjoint code for Matlab
- Scalar adjoint rules are not enough

2 Analysis

- Adjoint rules
- **Example statement**
- Intermediate canonicalization

3 Solution

- Recursive construction
- XSLT implementation

4 Results and Conclusion

- An example
- Conclusion

Example statement

- Consider the statement: $z = \sin(a * b) * c$

Syntax tree

Outline

1 Motivation

- Generating adjoint code for Matlab
- Scalar adjoint rules are not enough

2 Analysis

- Adjoint rules
- Example statement
- **Intermediate canonicalization**

3 Solution

- Recursive construction
- XSLT implementation

4 Results and Conclusion

- An example
- Conclusion

Canonicalized statement

- Canonicalization: $s = a * b$, $t = \sin(s)$, $z = t * c$

Syntax trees

Adjoint canonicalized statements

- Reverse adjoint statements:

$$\bar{t} = \bar{z} * c^T, \bar{s} = \cos(s) .* \bar{t}, \bar{b} += a^T * \bar{s}$$

Syntax trees

Putting it back together

- Single adjoint statement: $\bar{b} += a^T * (\cos(a * b) .* (\bar{z} * c^T))$

Merged syntax tree

Outline

1 Motivation

- Generating adjoint code for Matlab
- Scalar adjoint rules are not enough

2 Analysis

- Adjoint rules
- Example statement
- Intermediate canonicalization

3 Solution

- **Recursive construction**
- XSLT implementation

4 Results and Conclusion

- An example
- Conclusion

Observations

- The outermost $*$ -operator has the adjoint of the statement LHS at the adjoint position.
- The second level operator `sin` has at the adjoint position the expression sub-tree that was produced by the outermost operator.
- The evaluation order is inverted.

Recursive procedure

- Consider a statement $z = e$, assigning expression $e(x)$ to z . What is the adjoint expression w.r.t. x for that statement.
- Let $a_1 = \text{adjexp}(e, a_0)$ be the adjoint expression of the outermost operation in expression e , where $a_0 = \bar{z}$.
- Then, $a_2 = \text{adjexp}(\text{active-child}(e), a_1)$ is the adjoint expression of the second level operator, where active-child selects the child of the top along the path to variable x .
- Finally, a_k is the adjoint of the expression e w.r.t. variable x , where k is the depth of x in e .

Results and Conclusion

- An example
- Conclusion

Recursive template calls

- Traverse the expression tree in top down order with `apply-template`
- Pass along two parameters
 - `wrt` – id of variable node in the expression
 - `adj` – adjoint constructed so far
- `xsl:apply-templates` to that child which has the node with id `$wrt` among its descendant-or-self:..
 - `wrt` – `$wrt`
 - `adj` – new expression according to rule for current node, inserting `$adj` at the adjoint position of the rule

Template For Sine

```

<xsl:template match="call[id=_'sin']" mode="diff">
  <xsl:param name="wrt"/>
  <xsl:param name="adj"/>
  <xsl:apply-templates select="*[2]/*" mode="diff">
    <xsl:with-param name="wrt" select="$wrt"/>
    <xsl:with-param name="adj">
      <binary op=".*">
        <call>
          <id>cos</id>
          <xsl:apply-templates select="*[2]"/>
        </call>
        <xsl:copy-of select="$adj"/>
      </binary>
    </xsl:with-param>
  </xsl:apply-templates>
</xsl:template>
  
```

Template For Multiplication

```

<xsl:template match="binary[@op='_*']" mode="diff">
  <xsl:param name="wrt"/>
  <xsl:param name="adj"/>
  <xsl:variable name="which"
    select="*[descendant-or-self::*[generate-id(.)=_$wrt]]"/>
  <xsl:apply-templates select="$which" mode="diff">
    <xsl:with-param name="wrt" select="$wrt"/>
    <xsl:with-param name="adj"/>
    <xsl:choose>
      <xsl:when test="count($which/following-sibling::*)">
        <adjoint-left-multiplication>
          <xsl:copy-of select="$which"/>
          <xsl:copy-of select="$adj"/>
          <xsl:copy-of select="*[2]"/>
        </adjoint-left-multiplication>
      </xsl:when>
      <xsl:otherwise>
        <!-- ... -->
      </xsl:otherwise>
    </xsl:choose>
  </xsl:with-param>
</xsl:apply-templates>
</xsl:template>
  
```

Template For Variable Nodes

```
<xsl:template match="var" mode="diff">
  <xsl:param name="wrt" />
  <xsl:param name="adj" />
  <xsl:choose>
    <xsl:when test="generate-id()=id($wrt)">
      <xsl:copy-of select="$adj" />
    </xsl:when>
    <xsl:otherwise>
      <literal>0</literal>
    </xsl:otherwise>
  </xsl:choose>
</xsl:template>
```

Template For Statement

```

<xsl:template match="binary[@op_='']" mode="adjoint">
  <!-- pop variables, ... -->
  <xsl:apply-templates mode="adjoint-assignment"
    select="*[2]/descendant-or-self::var">
    <xsl:with-param name="this" select="."/>
  </xsl:apply-templates>
  <!-- zero adjoint of variable written, ... -->
</xsl:template>

<xsl:template match="var" mode="adjoint-assignment">
  <xsl:param name="this" />
  <xsl:param name="adj">
    <xsl:apply-templates select="ancestor::binary[@op_='']*[1]"
      mode="adjoint-var-of-statement"/>
  </xsl:param>
  <xsl:variable name="myid" select="generate-id()" />
  <adjoint-increment>
    <target>
      <xsl:apply-templates select="(parent::array|.)[1]" />
    </target>
    <incr>
      <xsl:apply-templates select="$this/*[2]" mode="diff">
        <xsl:with-param name="wrt" select="generate-id(.)" />
        <xsl:with-param name="adj" select="$adj" />
      </xsl:apply-templates>
    </incr>
  </adjoint-increment>
</xsl:template>

```

Outline

- An example
- Conclusion

Example: A Times B Times C

```
function z = mult3(a, b, c)
    z = a * b * c;
end
```

```
function [a_a, a_b, a_c, nr_z] = a_mult3(a, b, c, a_z)
    z = a * b * c;
    nr_z = z;
    [a_a a_b a_c] = a_zeros(a, b, c);
    a_a = a_a + a_z*(b * c).';
    a_b = a_b + a.'*a_z*c.';
    a_c = a_c + b.'*a.'*a_z;
end
```

```
admproc -s adjoint--reductions='no' --nocanonicalize mult3.m
```

Outline

1 Motivation

- Generating adjoint code for Matlab
- Scalar adjoint rules are not enough

2 Analysis

- Adjoint rules
- Example statement
- Intermediate canonicalization

3 Solution

- Recursive construction
- XSLT implementation

4 Results and Conclusion

- An example
- Conclusion

Conclusion

- Adjoint of arbitrarily nested expressions
- Ability to turn off code canonicalization
- Ability to generate code for only scalars or only matrices
- Simple implementation in XSLT

Outlook

- Represent derivative rules in one format for both forward and reverse?
- Handle cases where adjoints are given by algorithm, not an expression
